Breast cancer screens leads to 'unnecessary treatment'

By James Gallagher
Health and science reporter, BBC News

3 April 2012 | Health

Share

Up to one-in-four breast cancers detected by screening would never have gone on to be fatal or cause any symptoms, US researchers say.

Their study based on 39,888 women in Norway said between 15% and 25% of breast cancers were "overdiagnosed".

To screen or not to screen?

Call for change to breast cancer screening approach

By Pippa Stephens
Health reporter, BBC News

22 March 2014 | Health

Share

SCIENCE PHOTO LIBRARY

A different approach could help determine the severity of breast cancer cells, the study said

Almost one-third of women are at a higher risk of developing breast cancer and should be screened more than once every three years, a study says.

Cancer Survivor or Victim of Overdiagnosis?

By H. GILBERT WELCH NOV. 21, 2012

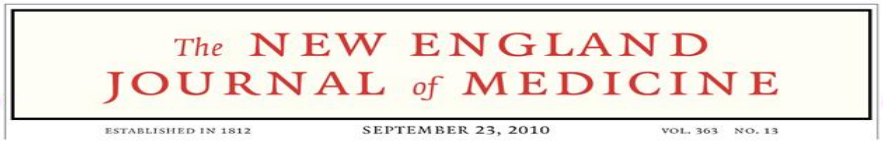
Hanover, N.H.

FOR decades women have been told that one of the most important things they can do to protect their health is to have regular mammograms. But over the past few years, it's become increasingly clear that these screenings are not all they're cracked up to be. The latest piece of evidence appears in a study in Wednesday's New England Journal of Medicine, conducted by the oncologist Archie Bleyer and me.

The study looks at the big picture, the effect of three decades of mammography screening in the United States. After correcting for underlying trends and the use of hormone replacement therapy, we found that the introduction of screening has been associated with about 1.5 million additional women receiving a diagnosis of early stage breast cancer.

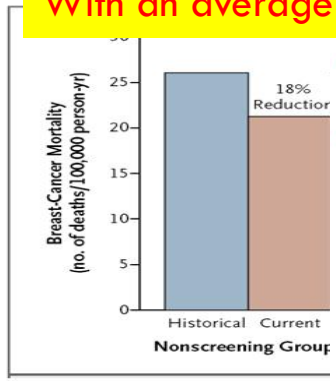
Fallacy in BC mass screening

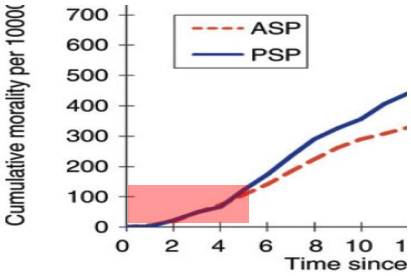
1. Short follow-up time: without lead-time consideration



Effect of Screening Mammography on Breast-Cancer Mortality in Norway

With an average follow-up of 2.2 years





Lead-time period

前導期偏差(lead-tim

2. Breast Cancer mixed: diagnosed before screening program, but died after program implementation

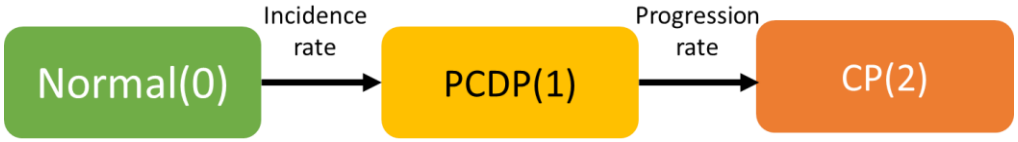
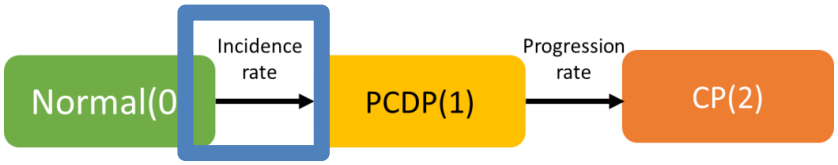
three-state Markov model



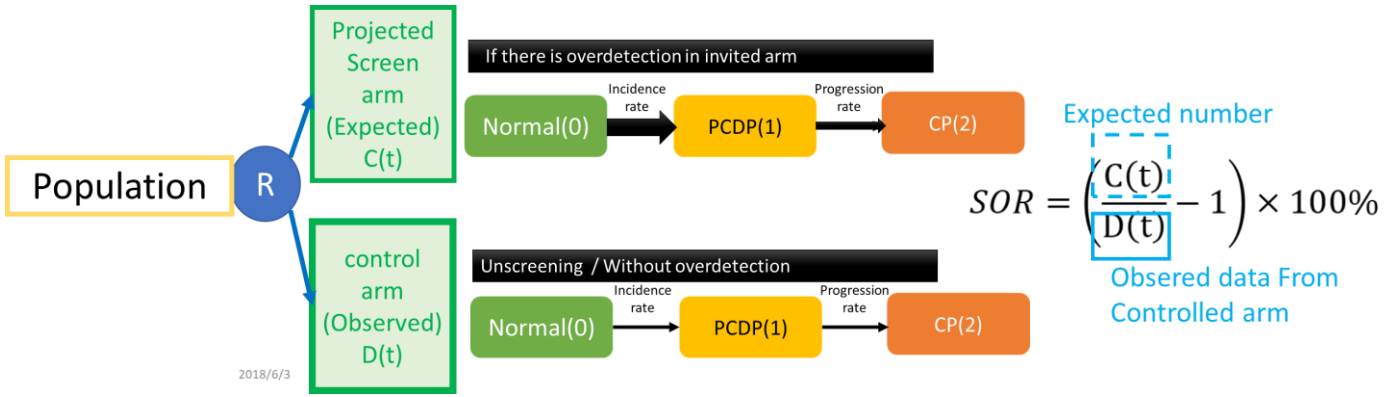
PCDP is unobservable in the control arm!



Estimated results on the transition rates of CRC based on three-state Markov model

Parameters	**UK** (Nottingham)	**Demark** (Funen)	**Taiwan**
Incidence rate	0.00147	0.00172	0.00096
(Normal→PCDP) (per person-year)	(0.00136, 0.00159)	(0.00155, 0.00189)	(0.00085, 0.00107)
Progression rate	0.3475	0.4433	0.1858
(PCDP →Clinical) (per year)	(0.2437, 0.4513)	(0.3226, 0.5639)	(0.0488, 0.7068)
Sensitivity of PCDP CRC	53.40%	52.05%	82.23%
	(34.26%, 69.55%)	(35.53%, 68.56%)	(46.82%, 96.05%)

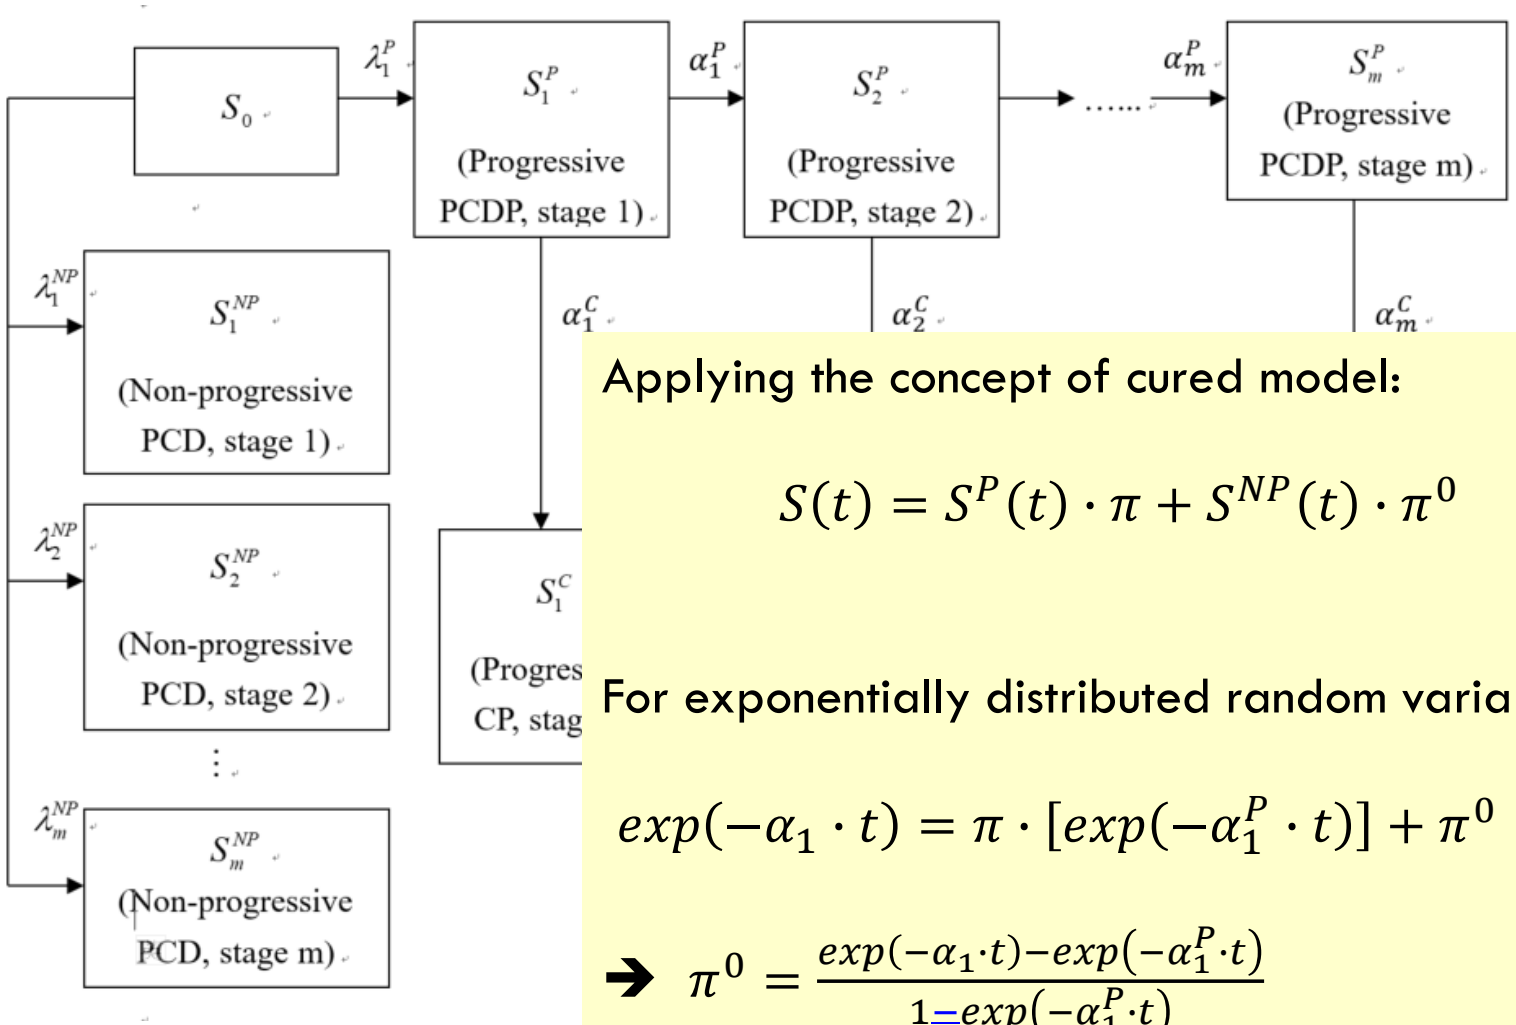
*CRC: colorectal cancer PCDP: pre-clinical detectable phase



Estimated results on standardized Over-detection ratio (SOR) based on the three-state Markov model and expected and observed frequencies of colorectal cancer for control group.

Study	Expected CRC, C(t)	Observed CRC, D(t)	SOR (%) (95% CI)
Nottingham, UK	931.26	856	8.79%(8.28,9.65)
Funen, Denmark	528.06	483	9.33%(8.81,10.20)
Taiwan	3656.63	3416	7.05%(6.56,7.89)

Coxian Phase-Type Markov Process



Applying the concept of cured model:

$$S(t) = S^P(t) \cdot \pi + S^{NP}(t) \cdot \pi^0$$

For exponentially distributed random variable

$$exp(-\alpha_1 \cdot t) = \pi \cdot [exp(-\alpha_1^P \cdot t)] + \pi^0$$

➔ $$\pi^0 = \frac{exp(-\alpha_1 \cdot t) - exp(-\alpha_1^P \cdot t)}{1 - exp(-\alpha_1^P \cdot t)}$$

Estimated natural history of breast cancer with and without consideration of over-detection, Swedish Two-County Trial (Kopparberg) 1977-1985

Parameters	With consideration of over-detection		Without consideration of over-detection	
	Estimate	95% CI	Estimate	95% CI
No detectable disease → progressive PCDP (λ_1^P)

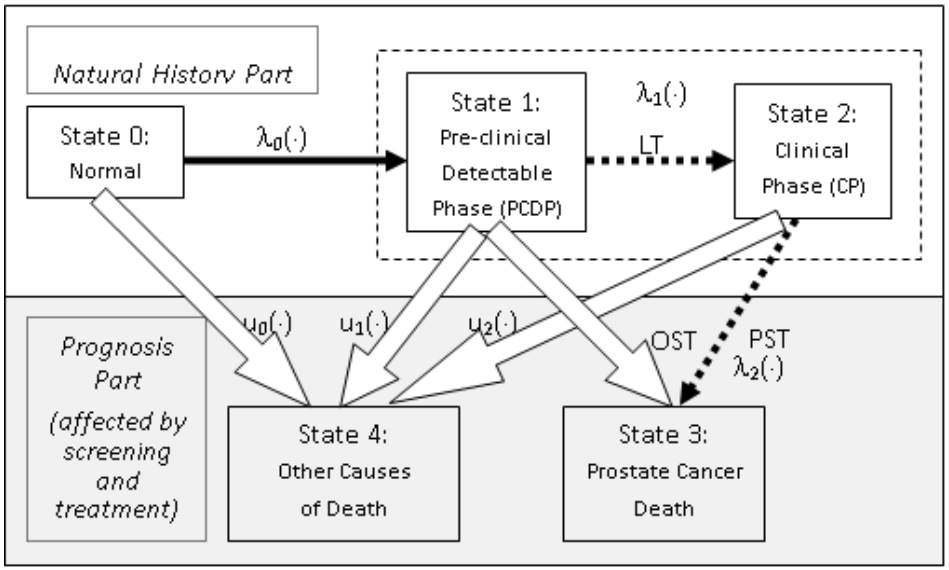
Mover-Stayer Model for Over-detection

(A)



(B)

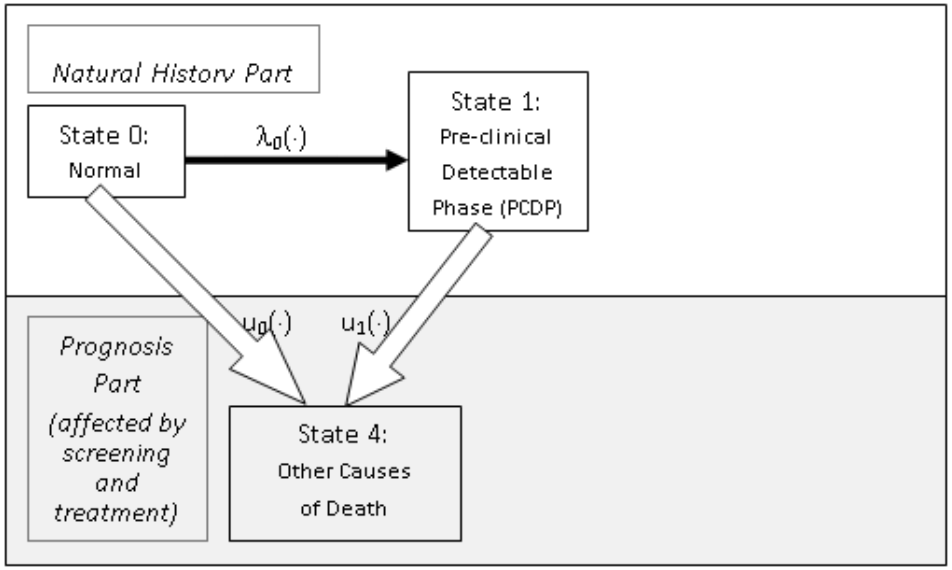


Fig. Diagrams of Markov models of natural history and prognosis of prostate cancer for lead-time, length bias, and overdetection adjustment.

(A) A Markov model combining the natural history and prognosis of prostate cancer. The model is also the same with the one for the **progressive** prostate cancer, "**mover**".

(B) A Markov model for the **non-progressive** prostate cancer, "**stayer**". White arrows denote the direct observation from the follow-up. Dotted arrows denote the unobserved transitions which decomposed the observed survival time into lead-time and post-lead-time survival time. OST: observed survival time; LT: lead-time; PST: post lead-time survival time.

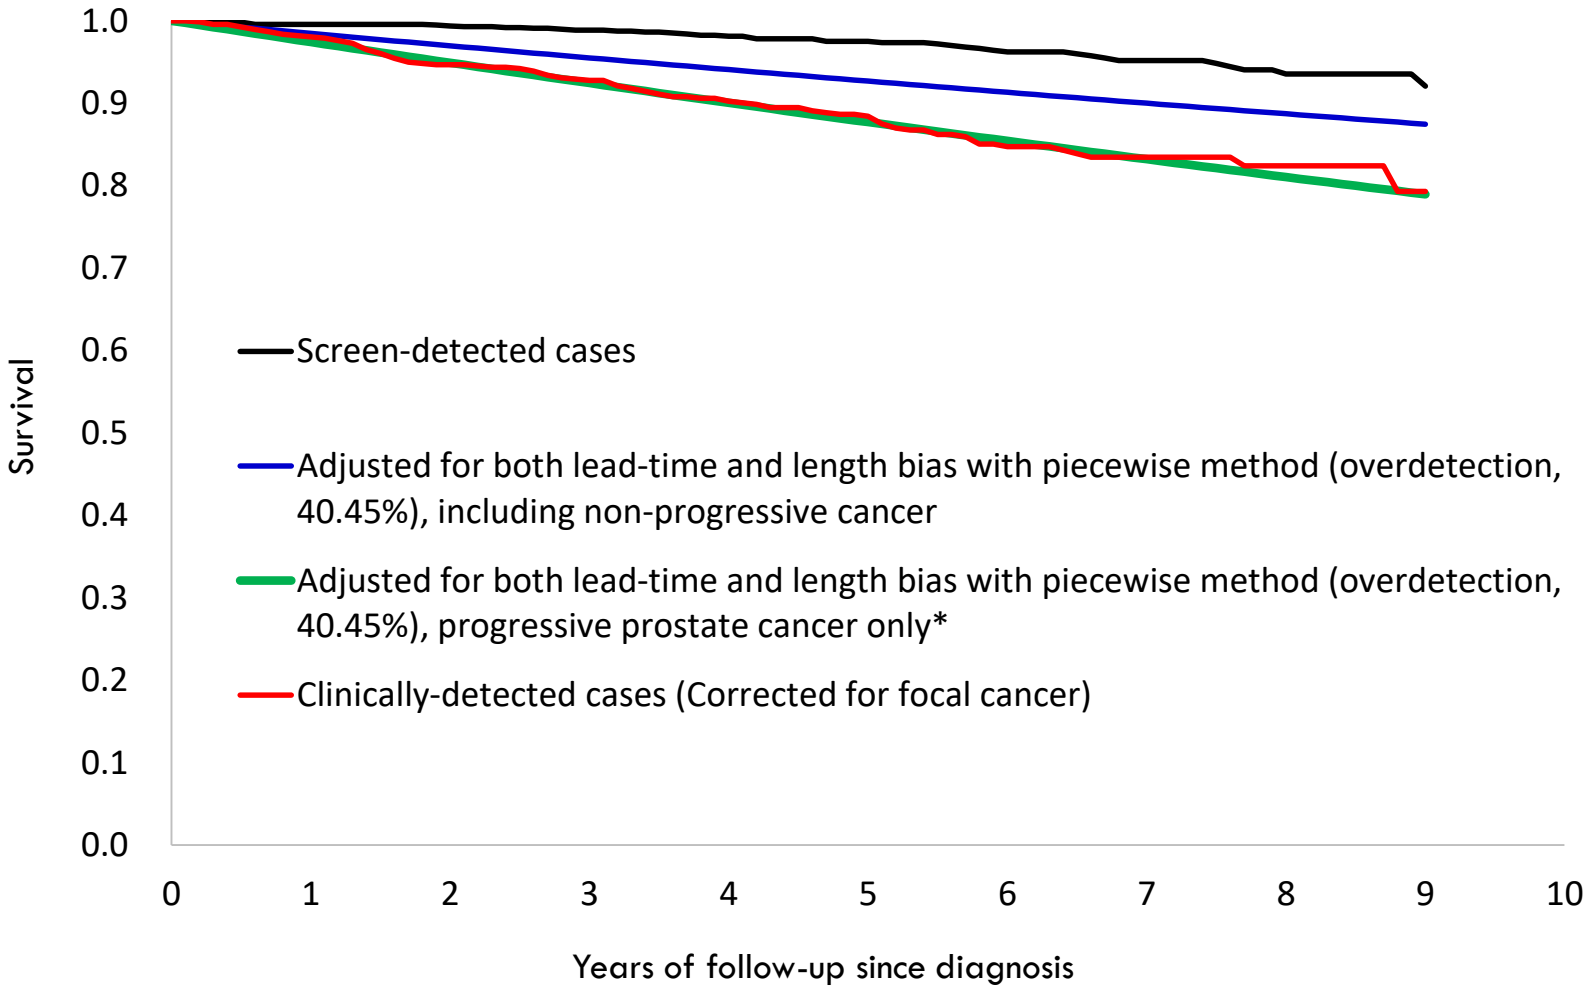
Estimated progression rates (per year) of prostate cancer cases, adjusted for both lead time and length bias, Finnish randomized controlled trial, 1996–2005.

Parameters	Estimate	95% CI[a)]
Extended model with over-detection adjustment[b)]		
The proportion of stayer	40.45%	31.95–48.95%
Pre-clinical incidence rate (λ_0) (Piecewise)		
55–58 y/o (λ_{01})	0.0009	0.0006–0.0013
59–62 y/o (λ_{02})	0.0047	0.0040–0.0054
63–66 y/o (λ_{03})	0.0069	0.0059–0.0078
67+ y/o (λ_{04})	0.0119	0.0108–0.0130
Annual progression rate (λ_1) (Piecewise)		
55–62 y/o (λ_{11}, λ_{12})	0.1376	0.0964–0.1787
63+ y/o (λ_{13}, λ_{14})	0.1340	0.1110–0.1570
Rate of prostate cancer death (λ_2) (Weibull)		
Scale (λ_{20})	2.01×10^{-5}	2.19×10^{-8}–4.02×10^{-5}
Shape (γ_2)	2.5086	2.2855–2.7318
Rate of other causes of death		
From normal (u_0)	0.0094	0.0087–0.0101
From PCDP (u_1)	0.0159	0.0127–0.0191
From CP (u_2)	0.0213	0.0164–0.0261

a) CI, confidence interval.
b) The proportion of over-detection, 40.45%, was estimated using a mover–stayer model.

Results. Finish PSA screening for prostate cancer

The estimated proportion of over-detection was 40.45% by using a mover-stayer model



Wu et al, 2012 *Biom J.*

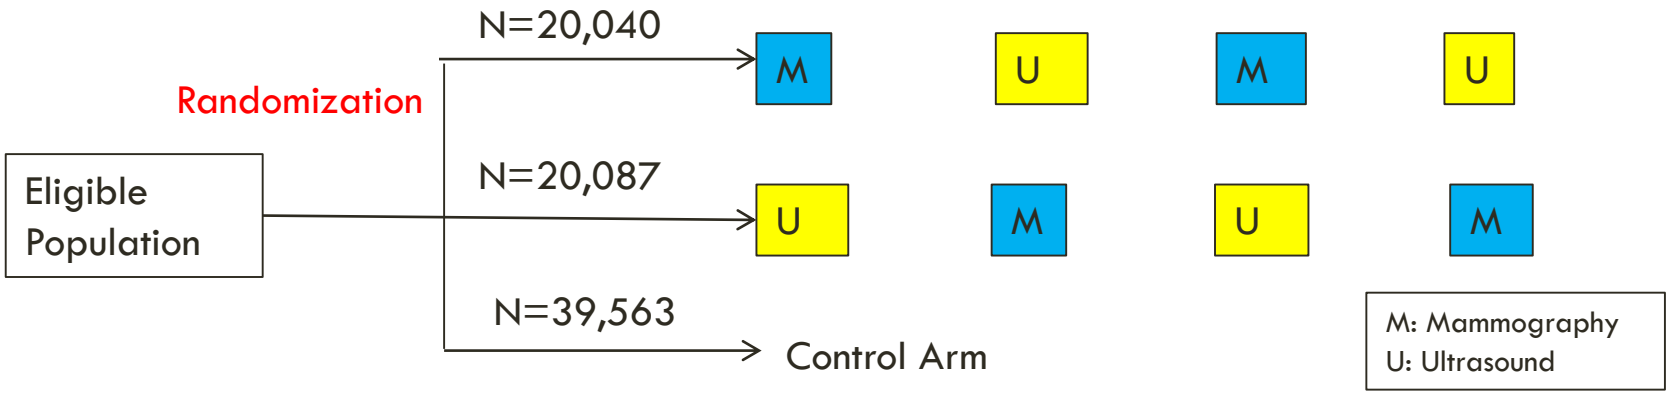
Impact of downstaging of breast tumor due to mammography screening on sensitivity and over-detection

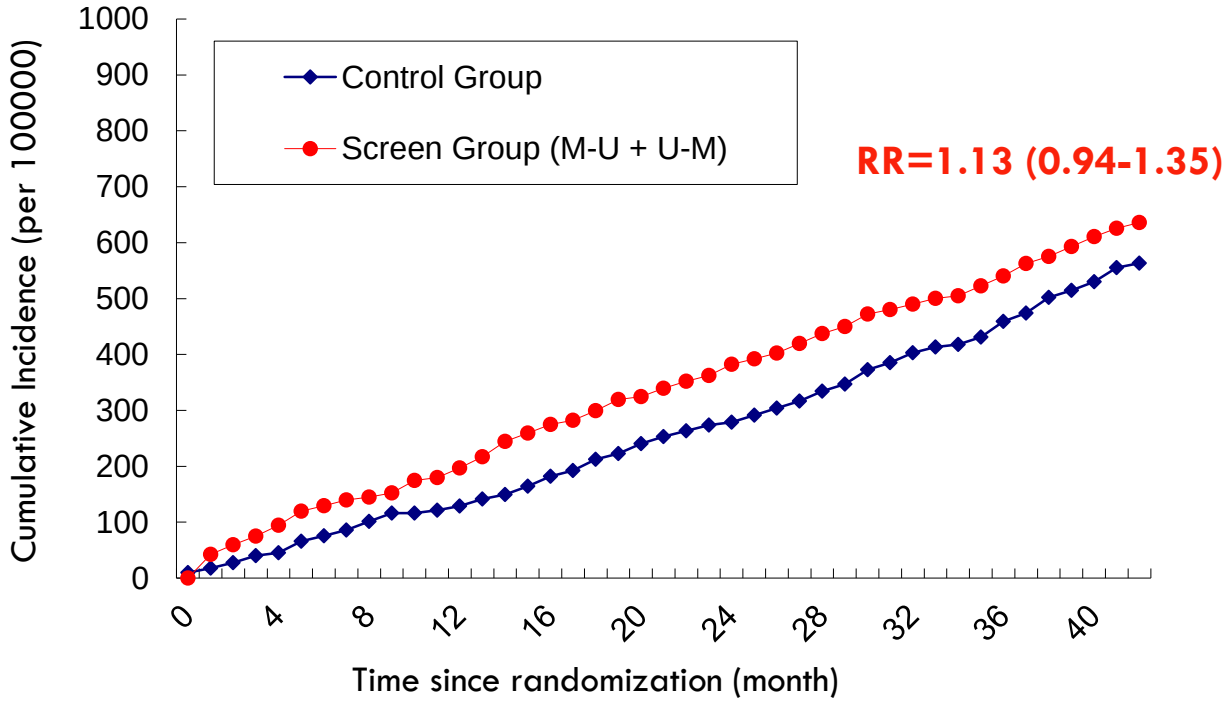
- Small tumor has a lower sensitivity than large tumor

- The proportion of overdiagnosis would be increased when the proportion of small breast tumour among screen-detected cases increase

Overdiagnosis with mammography in Taiwan

based on the Taiwanese randomized controlled trial for young women





Overdiagnosis with mammography in Taiwan

based on the Taiwanese Population-based service screening

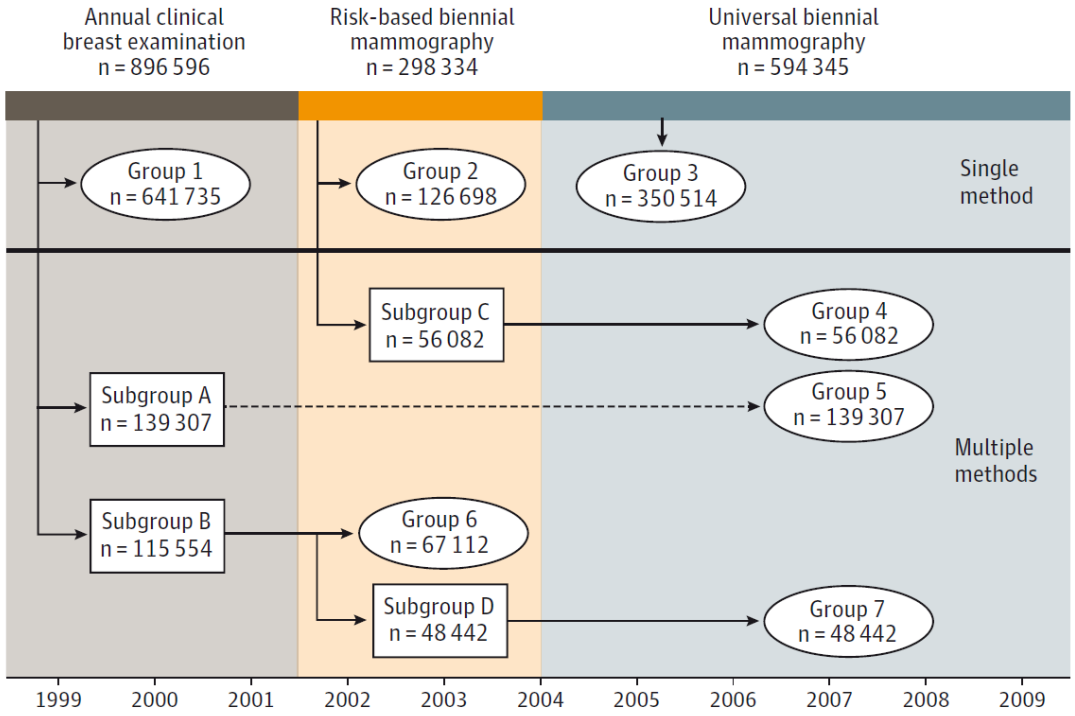
Population-Based Breast Cancer Screening With Risk-Based and Universal Mammography Screening Compared With Clinical Breast Examination

A Propensity Score Analysis of 1 429 890 Taiwanese Women

2016 *JAMA Oncology*

Amy Ming-Fang Yen, PhD; Huei-Shian Tsau, PhD; Jean Ching-Yuan Fann, PhD; Sam Li-Sheng Chen, PhD; Sherry Yueh-Hsia Chiu, PhD; Yi-Chia Lee, PhD; Shin-Liang Pan, PhD; Han-Mo Chiu, PhD; Wen-Horng Kuo, PhD; King-Jen Chang, PhD; Yi-Ying Wu, PhD; Shu-Lin Chuang, PhD; Chen-Yang Hsu, PhD; Dun-Cheng Chang, PhD; Shing-Lang Koong, PhD; Chien-Yuan Wu, MS; Shu-Lih Chia, MS; Mei-Ju Chen, MS; Hsiu-Hsi Chen, PhD; Shu-Ti Chiou, PhD



Total Incidence of breast cancer

Risk-based vs CBE:

RR=0.97 (95% CI: 0.92-1.03)

Mammography vs CBE:

RR=1.13 (95% CI: 1.08-1.18)

Conclusion

- The estimated proportion of over-diagnosis cases is affected by lead-time, sensitivity, and changing incidence, which causes the large disparity of over-detection.
- We clarified the estimation of over-diagnosis by the application of stochastic approaches taking three factors into account.
- Attention to over-diagnosis should be paid given a full-grown mature screening program.

THANKS FOR YOUR ATTENTION!
